ABSTRACT

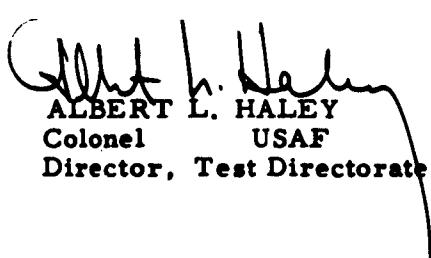

The purpose of the tests performed in the Chance Vought high-speed wind tunnel was to obtain force data to evaluate the static stability characteristics of the SLV-1B with 4-square-foot fins.

The model was instrumented with a six-component internal strain gage balance and two base pressure probes to determine the forces on the model. The model was then placed in the tunnel and tested in the Mach number range of 0.6 through 5.0, and a Reynolds number range of 6 million/ft. to 20 million/ft. The model attitude was varied from -10 to +10 degrees in the pitch plane.

The results obtained were force and moment data in the body axes; these results are presented in tabulated form with selected coefficients presented in plotted form.

1. INTRODUCTION.

This report presents data obtained from tests in the Chance Vought high-speed wind tunnel on a 0.098 scale model of the Standard Launch Vehicle (SLV)-1B with 4-square-foot fins. The test was conducted during the period from 16 October through 20 October 1962. Results are presented in tabulated form with selected coefficients presented in plotted form. A data analysis presentation is also included in section 8.

The model consisted of the same basic parts as the Scout Derivative Model (reference 1). The only changes were in the nose shape and the fin location. Tests were run on the complete body and also on the second stage. Provisions were included for the removal and adjustment of the fins. There were no fins on the second stage.

b. Test objectives.

To determine the static stability characteristics of the model in the Mach number range of 0.6 to 5.0.

3. NOMENCLATURE.

Forces and moments tending to produce a climbing right turn, clockwise roll maneuver are positive. Directions assume the model to be at $\phi = 0$ and the observer to be viewing upstream.

Coefficient data are presented in the body and stability axes.

4. DESCRIPTION OF FACILITY.

The Chance Vought Corporation high-speed wind tunnel is an atmospheric-exhaust, blow-down tunnel with a 4- by 4-foot test section size. The Mach number range of the tunnel is from 0.5 to 5.0. Air is stored in six tanks, with a total volume of 28,000 cubic feet, at a maximum pressure of 600 psia and a nominal temperature of 100 degrees Fahrenheit.

The circuit utilizes both supersonic and transonic test sections, each 4 by 4 feet in cross section and slightly over 5 feet long. For supersonic operation

a single-peak variable diffuser is placed downstream of the supersonic test section. For transonic operation the variable diffuser is removed from the circuit and replaced with a porous-wall, transonic-test section with 22 percent wall porosity. The transonic plenum is pumped by ejector action of the main tunnel airstream acting on controllable ejector flaps located downstream of the test section. Adjustable choking flaps, also located downstream of the test region, are utilized for subsonic Mach number adjustment. Figure 1 shows the general tunnel arrangement and identifies various areas within the facility.

5. MODEL AND INSTRUMENTATION.

The model tested was a 0.098 scale model of the Standard Launch Vehicle-1B with 4-square-foot fins. The model consisted of two basic bodies and two tail configurations. One body configuration was the second stage of the missile and was approximately 25 inches long. The other body configuration was the second stage with a first stage added to give it a total length of 49.09 inches. The fins were the same as those used on the Scout Derivative model described in reference 1. One set of fins had zero incidence angle and the other set had 3 degrees incidence angle to produce positive roll. Figures 2 and 3 show the installation of the two body configurations in the tunnel. Figure 4 shows the dimensions of the two bodies and the fins, and the orientation for each component.

Model forces were measured by the VB-13 six-component internal strain gage balance mounted on sting configuration number 1 with sting extension CVS54377 (reference 2). Figures 5 and 6 show the general arrangement and identify the sting sections. Two static pressure probes were located in the cavity of the body to measure base pressure. Each probe was connected to a separate pressure transducer to provide a backup system.

In addition to force balance and base pressure transducer outputs, tunnel parameters were also recorded. These parameters consisted of angle of attack, stagnation and static pressures, and stagnation temperature.

6. TEST PROCEDURES.

Preliminary preparations for the test included calibration of the VB-13 balance and the base pressure transducers. The sting and extension were

SLV-1B Second Stage Install

Figure 6. SLV-1B Second stage installation sketch.

Second Stage Installation Sketch

also calibrated for load deflections. Following installation of the model in the tunnel, additional load checks were made to ensure that the balance and data systems were functioning properly.

For test runs the tunnel was started with the model at zero angle of attack. When the flow was established the model was pitched to the maximum negative angle of attack, then back through zero to the maximum positive angle of attack, and returned to zero before the termination of the run. The angle of attack range through which the model was pitched was from a negative 10 degrees to a positive 10 degrees.

The test was conducted in the Mach number range of 0.6 to 5.0 and a dynamic pressure range of 900 to 2,500 psf.

Data cards were sampled before and after each run to obtain "wind on" and "wind off" data. Tare cards were also sampled before each run to permit a correction for model weight tare effects.

Data were sampled at the rate of 10 times per second for the body-alone and second-stage configurations, and 5 times per second when the fins were on the body. The data were digitized and recorded on magnetic tape. At the conclusion of each run, data cards were punched from the tape. The data cards were checked after each run to ensure satisfactory results. After the cards were accepted, the model and/or Mach number was changed. On-the-line data plotting was done by analog computer data reduction to parallel and check digitized data.

7. DATA REDUCTION.

Static force data were reduced by digital computer to obtain nondimensional force and moment coefficients about the body axes. A complete description of the data reduction procedure is presented in reference 3.

All coefficients were corrected for model weight tares, and angle of attack was corrected for sting and balance deflection. Axial force data are presented in three coefficient forms: axial force corrected for base pressure (C_A), axial force uncorrected for base pressure (C_{AU}), and axial force due to base pressure (C_{AB}).

Pitching moment was referenced to station 25.5 for the B₃ configurations and to station 14.1 for the B₄ configuration.

To present some means of determining data accuracies, static accuracies of the VB-13 balance are presented. The tabulated accuracies were obtained by computing a "root mean square" deviation between the applied and calculated loads over the maximum load range.

Results are as follows:

| <u>Component</u> | <u>Load</u> | <u>Coefficient</u> |
|------------------|-------------|--------------------|
| Normal force | 0.74 lb. | 0.0163 |
| Side force | 0.44 lb. | 0.0097 |
| Axial force | 0.35 lb. | 0.0077 |
| Rolling moment | 0.5° in-lb. | 0.0043 |
| Pitching moment | 0.74 in-lb. | 0.0054 |
| Yawing moment | 0.44 in-lb. | 0.0032 |

8. DATA ANALYSIS.

The experimental data show that the vehicle's first-stage static margin is approximately 15 inches less than originally estimated at Mach 3.8, which, for the nominal 76° trajectory, is the critical point. It appears that this is due to the fin effectiveness which is considerably lower than estimated. The vehicle's drag is higher transonically and lower supersonically than the original estimates. Fin rolling moment characteristics are generally as estimated except for lowered transonic effectiveness. At first-stage separation of the flight article, the nose cone and heat shield are jettisoned, exposing the payload. A model of this second stage was not available for these wind tunnel tests. The second stage as referred to in these tests consists of the vehicle forebody forward of body station 238.5 and is not representative of the actual vehicle second stage. This configuration was tested in an attempt to further define the body-alone center of pressure location and load distribution. The vehicle's second-stage static margin is more negative than estimated while the drag is less than estimated.

a. Wind tunnel tests.

The model tested was a 0.098 scale version of the SLV-1B. Transonic and supersonic tests were made on the first-stage configuration (with and without fins) and supersonic tests were made on the second-stage configuration to confirm the vehicle's estimated aerodynamic characteristics. The test runs on the first stage with and without fins were made to determine the fin effectiveness.

A standard six-component force balance was used to obtain normal force, pitching moment, axial force and rolling moment (yaw and yawing moments were negligible). The axial force (zero lift drag) data have been corrected to zero base drag.

The center of pressure locations are determined using the pitching moment and normal force derivatives; therefore, c.p. is directly effected by errors in both of these derivatives. The normal force and pitching moment errors are a function of several things; one of these being whether or not the normal force vector acts between the balance strain gages. For total vehicle tests, where the c.p. is well aft of the nose and between the balance strain gages, the c.p. location can be determined with ± 4 to 6 inches for the full-scale vehicle. However, for body-alone tests, where the c.p. is close to the nose of the vehicle and well outside of the balance strain gages this error can be increased by as much as a factor of 6. For these reasons, the center of pressure data for the body alone (and consequently the fin alone) from these tests should be used with caution. The values of normal force are much less sensitive to this effect than the computed values of center of pressure.

The test data for total vehicle C_{N_a} S are below predicted values at Mach numbers below Mach 4.0. The maximum variation is 18% at Mach 0.6. At Mach numbers from 3 to 5 the disagreement between predicted and measured is within the usual accuracy of prediction methods.

The experimental body-alone data are greater than estimated supersonically and less than estimated transonically. Part of the disagreement between experiment and prediction for the full first-stage configuration is due to this fact.

The C_{N_a} S of the fin plus carryover was determined by subtraction of body-alone C_{N_a} S from total-vehicle C_{N_a} S. Test data were consistently below the predicted values by 6% to 27% with the greatest disagreement occurring between Mach 2.0 to 3.0.

Test points produced a smooth curve with no unexpected variations in the pitching moment derivative.

The test data have been corrected by using a calculated friction drag and adding to that the pressure drag obtained from the wind tunnel and the calculated drag for six explosive bolt fairings.

Corrected wind tunnel data for the total vehicle are higher subsonically and transonically but lower supersonically than the estimates. The maximum variations were a 20% increase over the estimated data at Mach 1.0 and a 14% decrease below the estimated data at Mach 5.0.

Body-alone test data agree very well with the estimated data.

Zero lift fin drag, $(C_{D_0}S)_{fin}$, was obtained by subtracting the $C_{D_0}S$ of the body alone from the $C_{D_0}S$ of the total vehicle. The fin drag was underestimated subsonically and transonically and overestimated supersonically.

The c.p. variation for the total vehicle and body alone were computed from experimentally determined C_{m_a} and C_{N_a} values.

The test data (essentially rigid body) values of center of pressure for the total vehicle have the same trend as the predictions but indicate that the vehicle is less stable supersonically than estimated. The maximum decrease in static margin is about 15 inches or 0.484 body diameter. The maximum decrease in rigid body static margin occurred at Mach 3.8 and dropped from 35 inches of static margin to 20 inches.

In view of the problems of measuring the body-alone center of pressure no firm comments may be made concerning the disagreement between the experimental and predicted values. Since the body alone data are also used in determining the fin center of pressure the same caution must be taken when evaluating or using the fin center of pressure data.

Wind tunnel data and estimates for rolling moment coefficient are in generally good agreement. Test data did not show the predicted sharp peak transonically and are about 17% below the estimate in this region; for speeds in excess of Mach 2.0, test data are slightly higher. Supersonically the maximum difference between test and predicted values occurs at Mach 5.0 and is about 9.5%.

b. Second stage.

Second-stage aerodynamic data parameters were determined experimentally from Mach 2.0 to 5.0. The experimental normal force data agree very well with the predicted value at Mach 2.0. However, as the velocity increases, the test results show a gradual increase while the predicted value is constant for speeds in excess of Mach 3.0. The difference between the two values is a maximum of 25% at Mach 5.0.

A negative static margin of 75 inches was predicted at the Mach number for second-stage ignition; test data showed this negative static margin to be about 100 inches. In the range from Mach 3.0 to Mach 5.0, the maximum difference between test and prediction occurred at Mach 3.0 where the experimental static margin was 17% greater than predicted.

The experimental drag was lower than estimated over the entire test range. The maximum difference between predicted and measured drag occurred at Mach 4.0 where the test data were 14% below the predicted values.

9. CONCLUSIONS AND RECOMMENDATIONS.

The following conclusions may be derived from the wind tunnel tests on the SLV-1B model.

a. First stage.

The vehicle's normal force parameter is generally less than estimated with the largest differences occurring at transonic speeds. This difference arises partly from the body-alone characteristics and partly from the fin characteristics.

The rigid body center of pressure is forward of the estimates, thus resulting in a less stable rigid vehicle than estimated. This difference amounts

to about 15 inches decrease in static margin at a Mach number of 3.8. It appears that the primary reason for this effect lies in a lower fin effectiveness than estimated.

The test data show that the vehicle's zero lift drag parameter is less supersonically and greater transonically than the estimated values. Differences between fin-measured and estimated drags essentially account for these differences.

Estimated center of pressure variations due to the flexibility for the nominal 76° trajectory, when added to test data, show the vehicle to be unstable above Mach 3.0.

b. Second stage.

Normal force and zero lift drag force parameter estimates differed from test data by a maximum of 25 and 14% respectively between Mach 3.0 and 5.0. The parameters were under- and over-estimated respectively and the differences increased with Mach number.

Test data gave values for center of pressure 25 inches forward of the predicted location for an increase in the negative static margin of 33% at Mach 3.0. The difference decreases as Mach number increases resulting in a 15-inch difference at Mach 4.0.

STATIC STABILITY TESTS ON A 0.098 SCALE - STANDARD LAUNCH VEHICLE (SLV)-1B WITH 4-SQUARE-FOOT FIN AREA. Feb 63. 135P, incl illus, tables, 3 refs.</p> <p>I. AFSC Project 620-850B-7043 Unclassified Report</p> <p>II. Contract AF 29(601)-5603</p> <p>III. Vought Aeronautics, Div. of Chance Vought Corp., Dallas, Tex</p> <p>IV. C. E. Ziegler</p> <p>V. In ASTIA collection</p> | <p>The purpose of the tests performed in the Chance Vought high-speed wind tunnel was to obtain force data to evaluate the static stability characteristics of the SLV-1B with 4-square-foot fins. The model was instrumented with a six-component internal strain gage balance and two base pressure probes to determine the forces on the model. The model was then placed in the tunnel and tested in the Mach number range of 0.6 through 5.0, and a Reynolds number range of 6 million/ft. to 20 million/ft. The model attitude was varied</p> <p>(○)</p> | <p>1. SLV-1B--Stability 2. Pressure testing 3. Space vehicles--testing 4. Strain gages 5. Wind tunnel testing</p> <p>I. In ASTIA collection</p> | <p>The purpose of the tests performed in the Chance Vought high-speed wind tunnel was to obtain force data to evaluate the static stability characteristics of the SLV-1B with 4-square-foot fins. The model was instrumented with a six-component internal strain gage balance and two base pressure probes to determine the forces on the model. The model was then placed in the tunnel and tested in the Mach number range of 0.6 through 5.0, and a Reynolds number range of 6 million/ft. to 20 million/ft. The model attitude was varied</p> <p>(○)</p> | <p>1. SLV-1B--Stability 2. Pressure testing 3. Space vehicles--testing 4. Strain gages 5. Wind tunnel testing</p> <p>I. from -10 to +10 degrees in the pitch plane.
The results obtained were force and moment data
in the body axes; these results are presented in
tabulated form with selected coefficients pre-
sented in plotted form.
